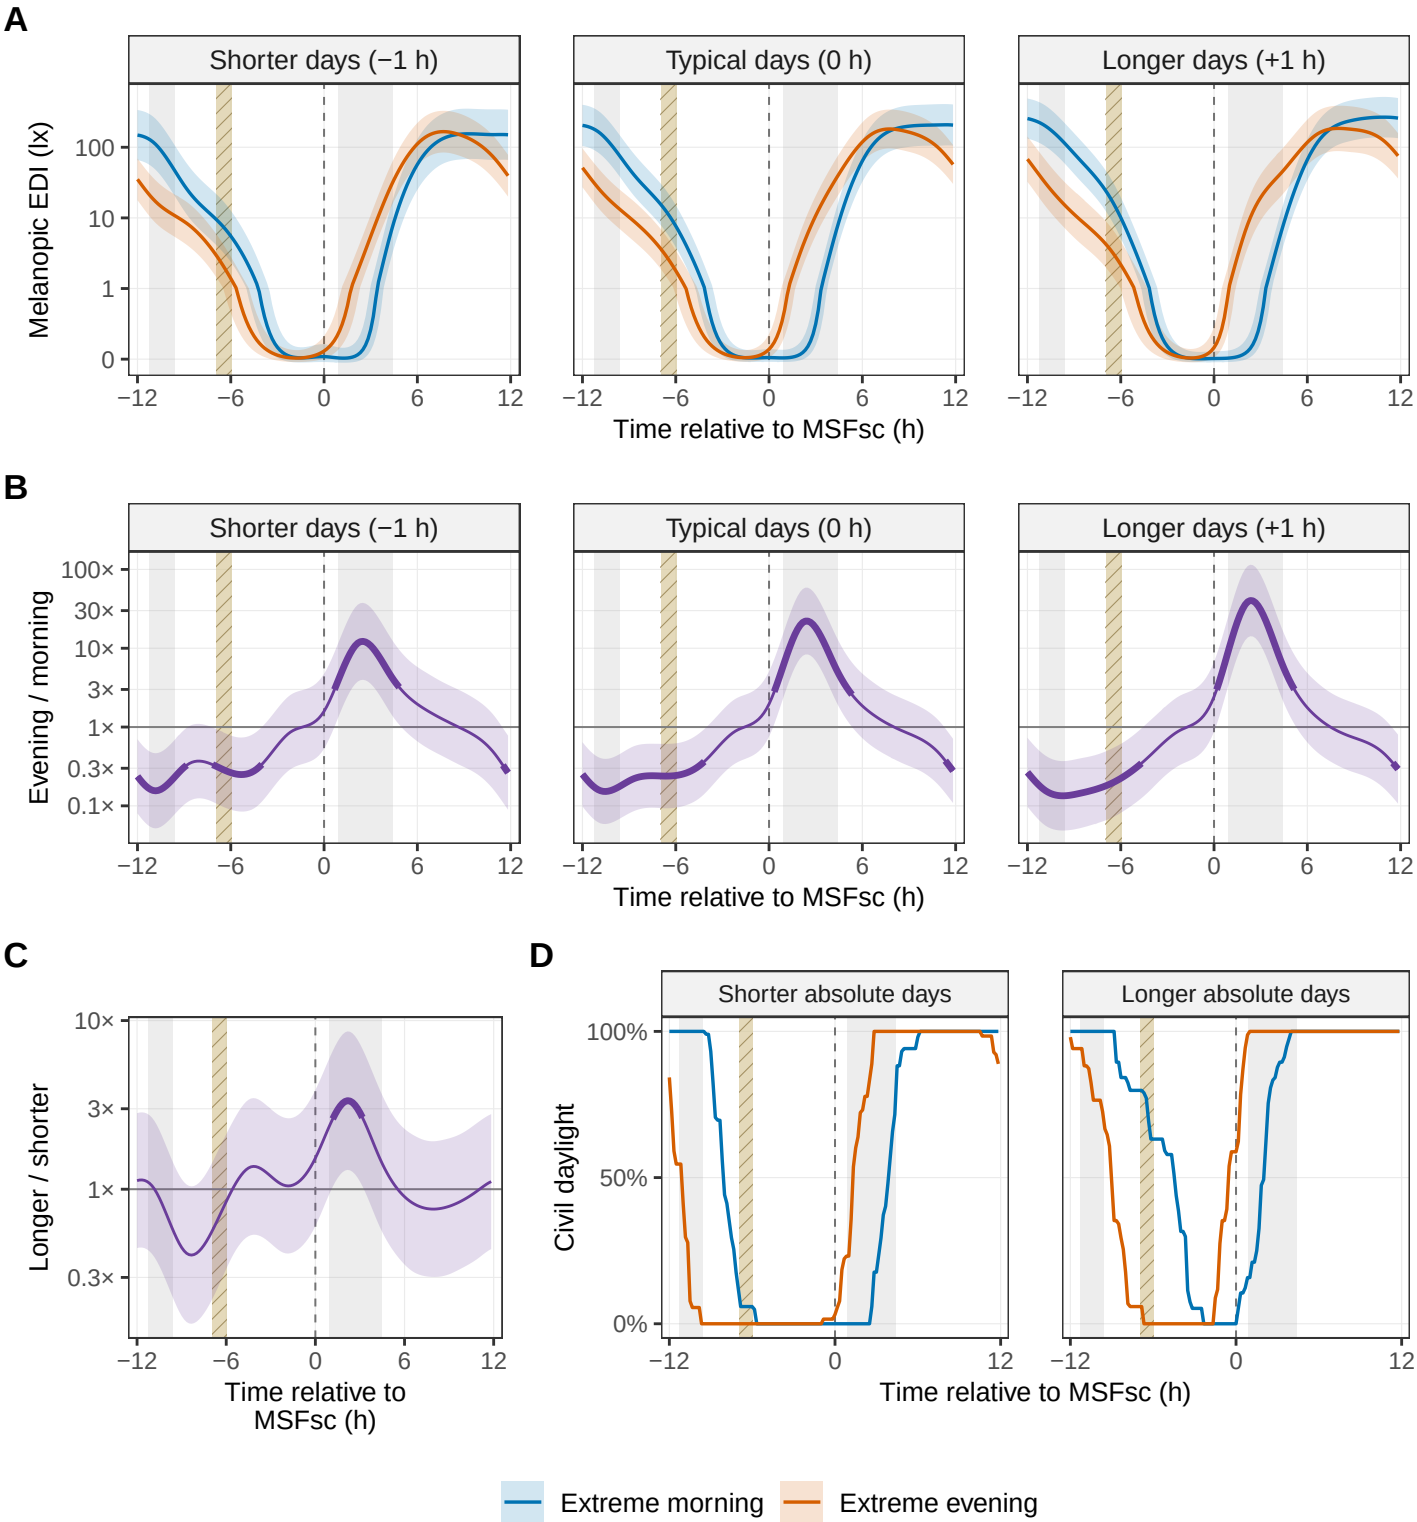
Daylength moderates the post−MSFsc chronotype contrast



A: extreme−group exposure curves at −1, 0 and +1 h of site−centered photoperiod. B: evening/morning ratios. C: longer/shorter ratio of those ratios. Bands are pointwise 95% intervals; bold sections exclude one with local support. D: civil daylight availability, using an absolute−daylength split at 13.25 h and equal participant and within−participant day weights. Borderless grey windows identify the primary exposure intervals; dashed vertical lines mark MSFsc at zero and stripes mark the DLMO reference interval. Exposure model: 140 participants, 778 days. Civil daylight: 70 extreme−group participants, 390 days.
