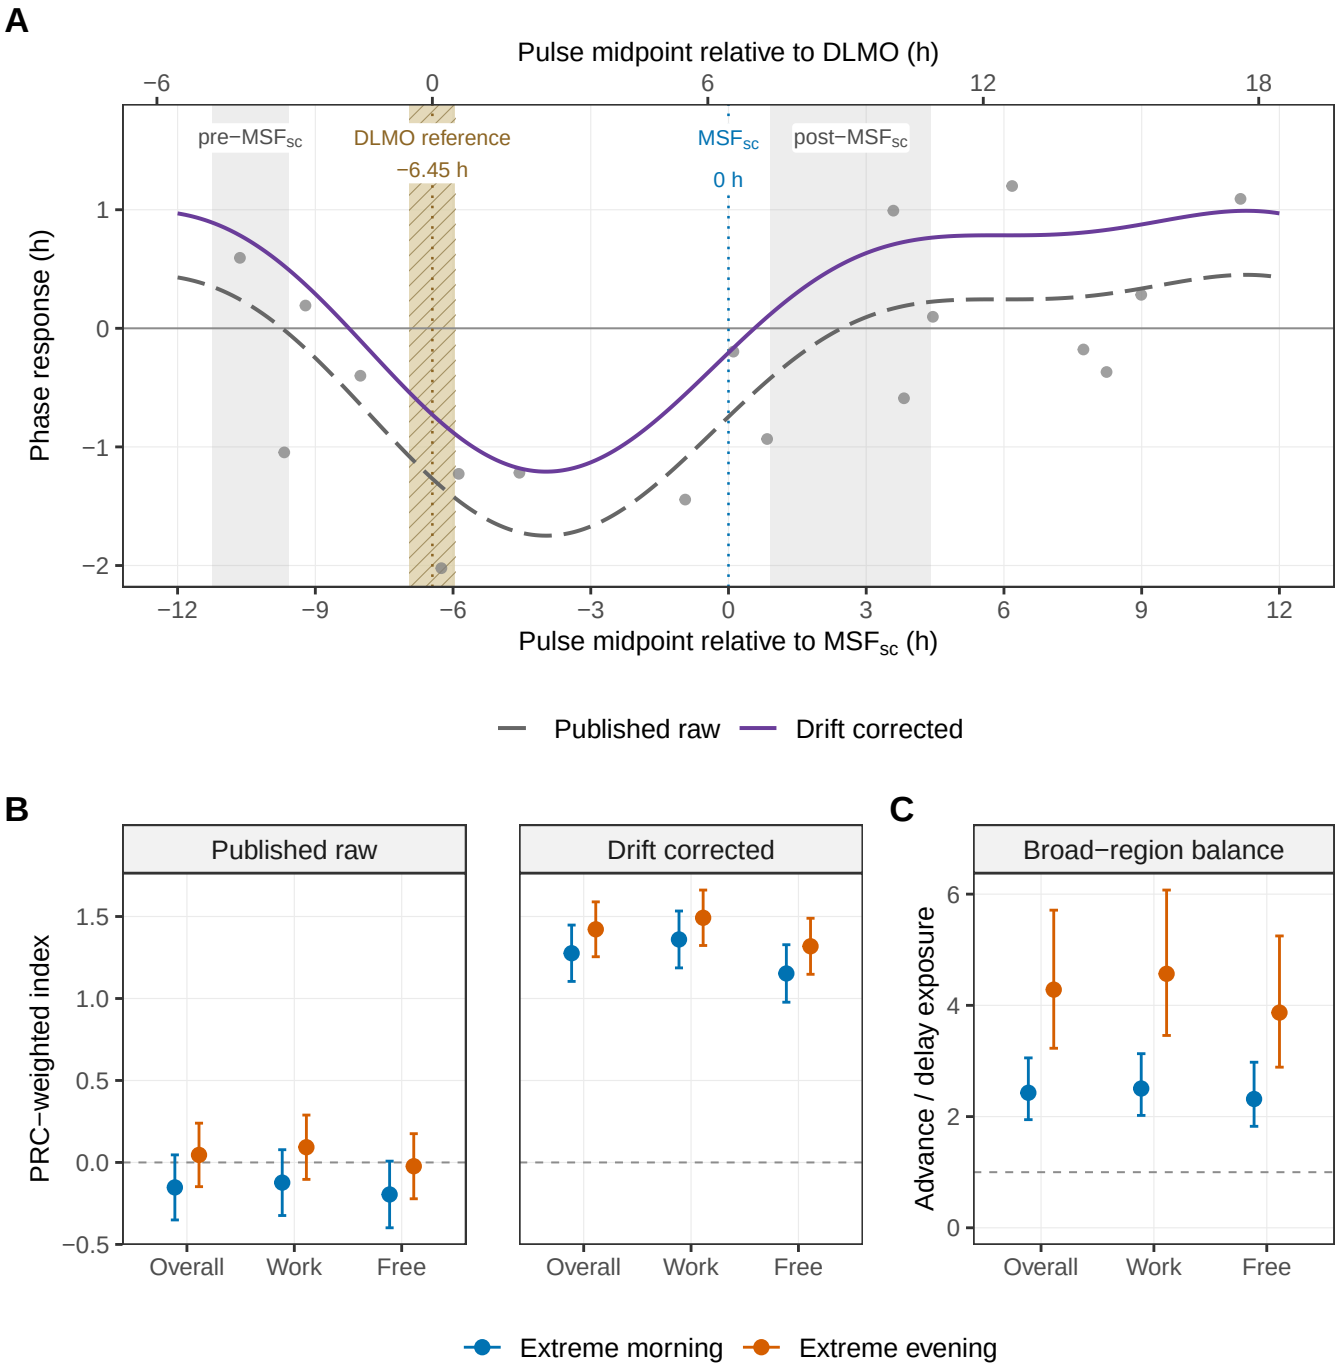
PRC weighting and advance−to−delay exposure balance



A: one−hour bright−white−light PRC from St Hilaire et al. (2012), reconstructed from 18 coordinates deposited by Walch et al. (2025). Dashed: published raw baseline; solid: drift corrected by +0.54 h. DLMO is aligned 6.45 h before MSFsc. B: extreme−group indices with the published raw PRC on the left and drift−corrected PRC on the right, using log10(melanopic EDI + 0.1) + 1. C: Emens−style sensitivity, dividing mean log10(fitted melanopic EDI + 1) in the advance region (DLMO −16 to −4 h) by the delay−region mean (−4 to +8 h). The line at one in C marks equal regional means within a group. Bars in B and C are 95% coefficient intervals; C uses percentiles of 10,000 joint draws. Grey windows are labelled pre−MSFsc and post−MSFsc; stripes mark the DLMO reference interval. Extreme groups: 70 participants, 390 days. These balances are not phase shifts in hours.
